Full Factorial Design Of Experiment

In statistics, a full factorial experiment is an experiment whose design consists of two or more factors, each with discrete possible values or "levels", and whose experimental units take on all possible combinations of these levels across all

such factors. A full factorial design may also be called a fully crossed design.

Factorial experiment - Wikipedia

Full Factorial Design leads to experiments where at least one trial is included for all possible combinations of factors and levels. This exhaustive approach makes it impossible for any

In designs where there are multiple factors, all with a discrete group of level settings, the full enumeration of all combinations of factor levels is referred to as a full factorial design. As the number of factors increases, potentially along with the settings for the factors, the total number of experimental units increases rapidly.

Design of Experiments - Full Factorial Designs | R-bloggers

A design in which every setting of every factor appears with every setting of every other factor is a full factorial design. A common experimental design is one with all input factors set at two levels each. These levels are called
